Anne Imberty,^d and Alexander Titz^{b,*}

Chronic infections with *Pseudomonas aeruginosa* are associated with the formation of bacterial biofilms. The tetrameric *P. aeruginosa* lectin LecA is a virulence factor and an anti-biofilm drug target. Increasing the overall binding affinity by multivalent presentation of binding epitopes can enhance the weak carbohydrate–ligand interactions. Low-nanomolar divalent LecA ligands/inhibitors with up to 260-fold valency-normalized potency boost and excellent selectivity over human galectin-1 were synthesized from D-galactose pentaacetate and benzaldehyde-based linkers in four linear steps.

Pseudomonas aeruginosa has been classified as a priority-1 pathogen by the World Health Organization due to its high antimicrobial resistance and the lack of new drugs to treat multidrug-resistant strains.¹ New strategies against these bacterial infections are being explored to overcome the current antimicrobial-resistance crisis.² The so-called anti-virulence therapy aims to neutralize bacterial virulence factors instead of increasing the selection pressure imposed by targeting essential cellular functions with antibiotics and thereby circumvents the advent of new resistances whilst preserving commensal bacteria.^{3,4} This strategy is investigated for *P. aeruginosa* infections by targeting its tetravalent lectins LecA and LecB.^{2,5,6} Both proteins are virulence factors regulated by quorum sensing, mediate bacterial host-cell adhesion and are essential structural components of *P. aeruginosa* biofilms.^{7–9} Whereas the best L-fucose/D-mannose-based LecB antagonists bind in the nanomolar range, monovalent D-galactose-based LecA inhibitors only

reach binding affinities in the mid to low micromolar range.^{10–15} In Nature, the rather weak lectin–carbohydrate binding is often overcome by increasing valency, and thus enhancing apparent affinity.^{16,17} Likewise, a boost in target-binding affinity was achieved with multivalent inhibitors of LecA and LecB.^{6,18} Since LecA is a tetramer and pairs of binding sites are geometrically favorably oriented, simultaneously binding divalent inhibitors can boost binding affinity through favorable binding entropy.^{19,20} Notably, Pieters and co-workers have developed divalent LecA inhibitors based on complex and rigid repeating units of carbohydrate-triazole spacers with potent binding affinities ranging from 12 to 220 nM,^{21–23} while a divalent inhibitor with a more flexible linker reaches an affinity of 80 nM.²⁴ In another report, an oligoproline-spaced digalactoside bound to LecA with K_d of 71 nM.²⁵

In this work, we aimed to develop divalent LecA ligands with a focus on drug-like properties, synthetic accessibility and linker simplicity enabling future lead optimization. Spacer length and flexibility are important factors contributing to the overall potency of multivalent inhibitors.⁶ An optimized linker connecting two neighboring binding sites within one LecA tetramer and avoiding unwanted cross-linking between different LecA tetramers is desired (Fig. 1a). β -Linked aryl aglycons increase the binding strength of galactosides to LecA by establishing CH– π interactions with His50.¹⁵ The co-crystal structure of LecA with phenyl β -D-galactoside (PDB code: 5d21) showed possible growth vectors in *meta*- and *para*-position at the phenyl aglycon (Fig. 1b).²⁶

Protein-templated dynamic combinatorial chemistry (DCC) is an elegant method for the identification of potent ligands from a combinatorial library of building blocks with suitable linking chemistry in presence of a given protein.^{27,28} To apply this method to LecA, we introduced hydrazides at the *para*- or *meta*-position of phenyl β -D-galactoside in order to allow for acylhydrazone formation in DCC. For this purpose, we chose two galactoside building blocks with *meta*- or *para*-attached hydrazides, **1m** and **1p**, and varied linker length, rigidity and number of rotatable bonds by systematically increasing the number of methylene units in the corresponding benzaldehyde

Fig. 1 Design of divalent LecA inhibitors accessible through a short synthetic route with acylhydrazone coupling chemistry. (a) Possible binding modes of divalent LecA inhibitors with desired linkage for two adjacent binding sites. (b) The crystal structure of phenyl β -D-galactoside in complex with LecA (pdb code: 5d21) and distances between two ligands within one pair of binding sites in LecA (from *meta* to *meta*: 23 Å, from *para* to *para*: 25 Å). (c) Building blocks of LecA inhibitors: *m/p*-hydrazinecarbonylphenyl β -D-galactopyranoside (**1m**, **1p**) and benzaldehydes **A–F**. Bis-benzaldehyde linkers **B–F** with systematic variation of length and number of rotatable bonds to optimize distance and flexibility.

spacers **B–F**. The corresponding monovalent control **A** was included (Fig. 1c).

Benzaldehydes **A** and **B** were commercially available and bis-benzaldehydes **C–F** were obtained in one step using 4-hydroxybenzaldehyde in a double nucleophilic substitution reaction on aliphatic α,ω -di-halogenated C1–C4 hydrocarbons under microwave irradiation (Scheme 1). Lewis acid-promoted glycosylation of methyl *meta*- or *para*-hydroxybenzoate with β -D-galactose pentaacetate (**2**) yielded glycosides **3m** and **3p** in 69% and 47% yield, respectively. Removal of the acetates under Zemplén conditions gave galactosides **4m** and **4p** quantitatively. Subsequent ester hydrazinolysis resulted in hydrazides **1m** and **1p** in very good yields. These building blocks were then used in DCC reactions in presence

Scheme 1 Synthesis of divalent LecA ligands and their monovalent analogs. *Reagents and conditions*: (i) 4-hydroxy benzaldehyde, K_2CO_3 , DMF, 70 °C, microwave, 3–10 h; (ii) methyl *m/p*-hydroxybenzoate, $BF_3 \cdot Et_2O$, CH_2Cl_2 , 0 °C – r.t., o.n.; (iii) NaOMe, MeOH, r.t., o.n.; (iv) $NH_2NH_2 \cdot H_2O$, MeOH, 70 °C, o.n. (v) formic acid, DMSO, r.t., 4 h, for **D5m**: DMSO/MeCN, for **F5m**: H_2O /MeCN.

of LecA: since the addition of LecA to the library caused precipitation, all divalent molecules were individually synthesized in absence of protein. Acylhydrazone formation of aldehydes **A–F** with excess hydrazide **1m** or **1p** under acidic conditions yielded the mono- and divalent LecA ligands **A5m–F5m** and **A5p–F5p**. The reduced solubility of the *meta*-series compared to the *para*-series and more difficult purifications could explain the lower yields despite nearly quantitative turnover during the individual reactions.

All synthesized galactosides, **A5m–F5m** and **A5p–F5p**, were then analyzed in the previously established competitive LecA binding assay based on fluorescence polarization (Fig. 2).¹¹ Monovalent *meta*-ligand **A5m** ($IC_{50} = 21.6 \pm 4.5 \mu M$) was twice as potent as its *para*-isomer **A5p** ($IC_{50} = 55.5 \pm 4.4 \mu M$). The divalent ligands **B5m–F5m** and **B5p–F5p** showed a very similar profile in the competitive binding assay with very similar IC_{50} values in the single-digit micromolar range and a very steep Hill slope of the fit. These observations are likely a result of reaching the lower assay limit since the low affinity of the fluorescent primary ligand ($K_d = 7.4 \mu M$) required a relatively high LecA concentration of 20 μM . Therefore, ligand affinities with orders-of-magnitude higher potencies than the primary competitively displaced ligand cannot be reliably determined.

To overcome the competitive binding assay's limitation, we analyzed all inhibitors in a direct LecA binding experiment using surface plasmon resonance (SPR). In case of the monovalent inhibitors **A5m** and **A5p**, rapid changes in the binding response during the association and dissociation phases were observed, indicating fast association/dissociation kinetics of the monovalent inhibitors to immobilized LecA (Fig. 3a and b). Due to this fast association/dissociation behavior, k_{on} and k_{off} for their interaction with LecA could not be accurately determined and affinity analysis was performed instead of determining K_d at steady-state binding. In SPR, the monovalent ligands **A5m** and **A5p** have K_d values of 4.9 ± 0.1 and $5.6 \pm 0.3 \mu M$, respectively (Table 1). The binding affinities for those monovalent compounds were validated using isothermal titration microcalorimetry (ITC) as an orthogonal method and similar values to SPR data were obtained (ITC: **A5m** $K_d = 2.7 \pm 1.3 \mu M$, **A5p** $K_d = 6.1 \pm 0.5 \mu M$, Table 1 and Fig. S1, ESI[†]). In both analyses, a *meta*-substitution of the phenyl aglycon in **A5m** resulted in higher affinities to LecA compared to the *para*-isomer **A5p**.

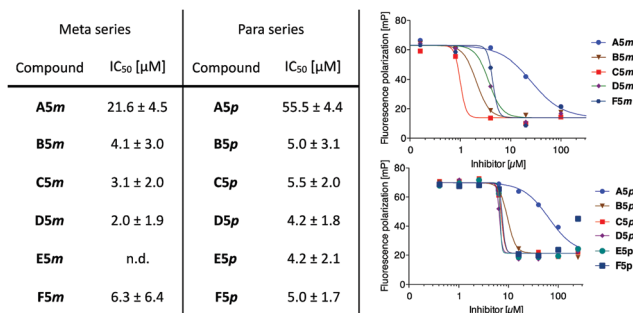

Fig. 2 Evaluation in a competitive binding assay. One representative titration is shown for each series (right) – steep titration slopes for divalent inhibitors indicate the lower assay limit was reached. Aver. and std. dev. from at least 3 independent titrations of triplicates each. n.d. = not determined.

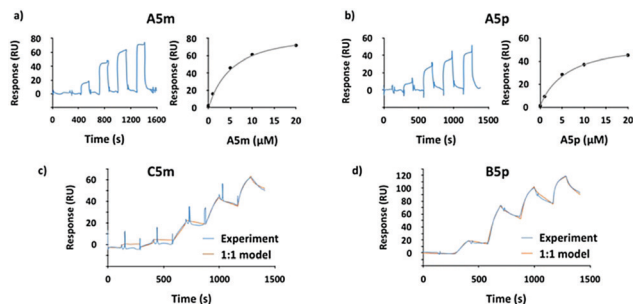

Fig. 3 SPR analyses of the interaction between the monovalent inhibitors (a) **A5m** and (b) **A5p**. The sensorgrams are shown on the left panel and the affinity analyses on the right. (c) Sensorgrams of the most potent divalent inhibitors from *meta*-series (**C5m**) and (d) from *para*-series (**B5p**) at five different concentrations (0, 10, 50, 100, 200 nM).

In contrast to the monovalent hydrazides, the SPR sensorgrams of the divalent inhibitors clearly indicated much slower association/dissociation of the compounds from LecA, demonstrating the benefit of divalent binding and enabling determination of kinetic parameters (k_{on} and k_{off}) as well as K_{d} (calculated from $k_{\text{off}}/k_{\text{on}}$, Fig. 3c, d and Fig. S2, ESI†). The divalent inhibitors **B5m–F5m** and **B5p–F5p** showed a strong increase in potency into the low nanomolar range (Table 1). In the *para*-series, compound **B5p** was the most potent ligand ($K_{\text{d}} = 10.8 \pm 1.0$ nM), with a 520-fold increase (260-fold valency-corrected) compared to its monovalent congener **A5p** ($K_{\text{d}} = 5600 \pm 300$ nM). The divalent *para*-ligands showed a slight decrease in potency with increasing spacer length, resulting from gradually decreasing k_{on} and increasing k_{off} (Table 1). In the *meta*-series, similar trends were absent. **C5m** with one central methylene unit had the optimal length and showed a K_{d} of 18.9 ± 1.6 nM. Shortening or increasing spacer length resulted in reduced affinities and surprisingly the second longest compound **E5m** was the least efficient inhibitor (K_{d} of 80.7 ± 11.4 nM). Comparing across the *meta*-series, the k_{on} values were surprisingly 2–4 times smaller for compounds **C5m** and **E5m**. The k_{off} values were gradually increasing going from **C5m–F5m**. The k_{off} for **B5m** was 5-times higher than that of **C5m**.

We then studied compound selectivity in binding experiments towards human galectin-1, a homodimeric lectin that specifically recognizes β -galactoside containing glycans such as Me- β -lactoside ($K_{\text{d}} = 187$ μM).²⁹ The most potent inhibitors

from the *para*- and *meta*-series, **B5p** and **C5m**, together with their respective monovalent counterparts (**A5p** and **A5m**), were analyzed by SPR for their interaction with human galectin-1. Neither the monovalent (at 250 μM) nor the divalent compounds (at 25 μM) had a detectable interaction with the immobilized galectin-1 (Fig. S3, ESI†).

Since we did not succeed in obtaining crystal structures of LecA complexed with the divalent inhibitors, we carried out modeling on pairs of *para*- and *meta*-compounds, selecting the high-affinity binder **C5m** and its *para*-counterpart **C5p**; and the longer, less active **E5m** and **E5p**. The dynamics of these four compounds were simulated in the free state and in the modeled complex with LecA. In the free state, the ligands adopted a broad range of semi-extended to fully extended conformations characterized by Gal:C1...Gal:C1 distances ranging from 20 to 31 Å at a cutoff of 5% frequency (Fig. 4a, solid curves). A distance close to the crystallographic value of 29 Å (PDB: 5d21) is desired for optimal divalent binding of LecA. In the longer compounds, **E5m** and **E5p**, there was a small population (around 5%) of folded conformations (see the peaks at 5 Å in Fig. 4a). The unfolding of these conformations prior to LecA binding may be in part responsible for their slower on-rate (k_{on}).

The four ligands modeled in complex with LecA showed a narrow distribution of the Gal:C1...Gal:C1 distances (Fig. 4a, dashed lines). **C5m**, **C5p** and **E5p** sampled distances of 28.9 ± 0.4 Å, 28.1 ± 0.9 Å, and 28.2 ± 0.7 Å, respectively, close to the 29 Å observed in crystal structures, thus indicating that the linker lengths are well-suited to bridge two LecA monomers. The narrow range for **C5m** (28–31 Å) may explain the lower affinity of shorter **B5m**. In contrast, **C5p** and **E5p** have larger range (26–31 Å) and shortening is beneficial such as in **B5p**. **E5m** with LecA displayed a higher mean distance of 30.2 ± 0.8 Å (range of 28 to 33 Å). Such longer *meta* linker pushes the two LecA monomers slightly apart, which is not favourable. The T-shaped CH- π interaction between His50 and the phenyl aglycon was observed with higher frequency for the *meta* compounds **C5m** and **E5m** compared to their *para* analogues **C5p** and **E5p** (Fig. 4b). On the opposite, the *para* ligands, **C5p** and **E5p**, preferentially adopted an inverted V-shape (Fig. 4c and d) in which their phenyl aglycons sampled a variety of arrangements with respect to His50 (parallel, diagonal, T-shape).

To conclude, we designed and synthesized highly potent divalent LecA inhibitors in four linear chemical steps from

galactose pentaacetate. These simple and rapidly accessible divalent inhibitors **B5m–F5m** and **B5p–F5p** have comparable or superior activity to the previously reported and structurally complex di- and multivalent LecA ligands. Monovalent analogs **A5m** and **A5p** showed binding to LecA in SPR and ITC experiments in the low micromolar range ($K_d = 2.7–6.1 \mu\text{M}$). Divalent display of these epitopes in **B5m–F5m** and **B5p–F5p** boosted binding affinity with LecA to low nanomolar values. Molecular dynamics simulations gave insights into the interplay of linker geometry and length for an optimal divalent binding. To the best of our knowledge, compound **B5p** with a K_d of 10.8 nM is the most potent divalent LecA ligand reported to date with confirmed selectivity for LecA over galectin-1. Due to the simplicity of our synthetic design and readily accessible building blocks, further fine tuning and optimization of drug-like properties can be readily implemented. Future optimization of these compounds targeting LecA may provide a treatment of biofilm-associated *P. aeruginosa* infections.
